PREFACE.

In presenting this Catalogue to Surgeons and the Medical Profession, we take this opportunity to thank them for their past support and recommendation.

We have endeavoured to make a complete List, but as many Instruments have been invented since we commenced, we were unable to include them, but shall be happy to answer any inquiry respecting them.

Our connection with Home and Foreign Instrument Makers being very extensive, we are able to procure any Instrument, invented or improved here or abroad, which our customers may require.

We believe that our prices will compare favourably with those of other Houses for Instruments of the best Materials and Workmanship, and by strict attention to Business we hope to merit the continuance of your favours.

KROHNE & SESEMANN,

*8, Duke Street, Manchester Square, W.; and at
241, Whitechapel Road, London, E.*

DIRECTIONS FOR CUSTOMERS ORDERING.

IN writing an Order please write Name and Address distinctly.

It is usual to send small Parcels per Post, and this is also the quickest method of forwarding. The rate is as follows :—

Parcels not exceeding	1 oz.	...	1d.
Do.	2 oz.	...	1½d.
Do.	4 oz.	...	2d.
Do.	6 oz.	...	2½d.
Do.	8 oz.	...	3d.
Do.	10 oz.	...	3½d.
Do.	12 oz.	...	4d.

Satisfactory references, or a remittance is required from a customer with whom we have not had the pleasure of doing business before.

Accounts Quarterly are charged NETT.

5 per cent. charged on accounts which have not been settled at the expiration of Thirteen Months.

5 per cent. Discount allowed for Prompt Cash off amounts of £1 and upwards.

CASES OF EYE INSTRUMENTS.

No. 1.

LEATHER CASE, WITH SPRING FASTENER.

Containing—Beer's Knife, Curette and Cystotome,
 Tyrrell's Hook, Broad Needle, Fine Needle, Iris
 Scissors, Iris Forceps, Cilia Forceps, Lachrymal
 Duct Probe, Critchett's Director and Speculum £2 15 0

No. 2.

MOROCCO CASE.

Containing—Two Beer's Knives, Broad Needle, Fine
 Needle, Angular Needle, Sharp Hook, Curette
 and Cystotome, Noye's Speculum, Straight
 Scissors, Curved Scissors, Set of Lachrymal
 Duct Probes and Director, Cilia Forceps, Iris
 Forceps and Fixing Forceps £4 0 0

No. 3.

MOROCCO CASE, LINED WITH SILK VELVET.

Containing—Two Beer's Knives, Two Graefe's Knives,
 Jaeger's Iridectomy Knife, Two Fine Needles,
 Two Broad Needles, Two Angular Needles,
 Curette and Cystotome, Double Scoop, Tyrrell's
 Hook, Spud and Gouge, Two Scissors, Cilia
 Forceps, Curved Iris Forceps, Straight Iris
 Forceps, Bowman's Probe, Critchett's Director,
 Spring Speculum, Speculum with stop screw,
 Improved Iris Forceps, Wecker's Iris Scissors ... £9 7 6

No. 4.

MOROCCO CASE, LINED WITH SILK VELVET.

Containing—Two Beer's Knives, Two Graefe's Knives,
 Two Jaeger's Knives, Two Secondary Knives,
 Two Broad Needles, Two Fine Needles, Two
 Angular Needles, Spud and Gouge, Curette and
 Cystotome, Fixateur, Tattooing Needle, Lachry-
 mal Duct Knife, Tyrrell's Hook, Stopped Needle,
 Strabismus Hook, Critchett's and Bowman's
 Scoops, Critchett's Director and Bowman's
 Probes, Straight Iris Forceps, Curved Iris
 Forceps, Two Entropium Forceps, Cilia Forceps,
 Fixing Forceps, Strabismus Scissors, Angular
 Scissors, Curved Scissors, Spring Speculum,
 Speculum with stop screw, Eye-lid Retractor,
 Needles and Silk £12 0 0

No. 5.

MOROCCO CASE, LINED WITH SILK VELVET.

Containing—Two Beer's Knives, Two Graefe's Knives,
 Two Jaeger's Iridectomy Knives, Two Jaeger's
 Cataract Knives, Two Secondary Knives, Three
 Broad Needles, Three Fine Needles, Two Curved
 Needles, One Stopped Needle, Two Angular
 Needles, Curette and Cystotome, Double Spud,
 Gouge, Critchett's and Bowman's Scoop, Tatto-
 oing Needle, Fixateur, Probe and Paracentesis
 Needle, Lachrymal Duct Knife, Guarded
 Lachrymal Duct Knife, Two Small Scalpels, Iris
 Hook, Strabismus Hook, Two Entropium For-
 ceps, Wyld's Tarsal Tumor Forceps, Straight
 Iris Forceps, Curved Iris Forceps, Improved
 Iris Forceps, Noye's Iris Scissors, Capsular
 Forceps, Strabismus Scissors, Angular Scissors,
 Curved Scissors, Curved on Flat Scissors, Teale's
 Instrument for suction of soft Cataract, Critchett's
 Director and Bowman's Probes, Spring Speculum,
 Weiss's Speculum, Eye-lid Retractor, Needles
 and Silk £21 10 0

8, DUKE STREET, MANCHESTER SQUARE, W.,

Arm Rest for
Mahomed's Case, containing Sphygmograph and the necessary appliances for taking and fixing tracings, the lid of which forms an arm rest
	7	10	0
	1	1	0
	10	10	0

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

DIRECTIONS FOR THE APPLICATION OF MAHOMED'S SPHYGMOGRAPH.

To obtain a perfect tracing the following directions must be carefully observed :—

1. Place the arm of the patient on a double inclined splint, the under surface of which forms an angle of 135° ; let it lie in as unrestrained and comfortable a position as possible.

2. Apply with great care the centre of the ivory pad of the spring exactly over the centre of the artery.

3. The part of the radial artery chosen for the application of the instrument, should be that which lies to the inner side of the Styloid process of the Radius over the upper fibres of the anterior ligament of the wrist joint.

4. When thoroughly satisfied that the pad is exactly over the artery, strap the instrument on to the arm very firmly, with *inelastic* bands, so that no shifting is possible.

5. Note the amount of pressure that is required to wholly extinguish the pulse.

6. On a trial slip of smoked paper, discover with which pressure you get the most perfect tracing, viz.:—The highest upstroke, and the best marked “percussion wave.”

7. Take care that the smoked paper is evenly and tightly stretched upon the slide, and that the writing lever does not press too firmly against it, so as to impede its free movement.

8. Never be satisfied with the first tracing obtained, always reapply the Sphygmograph two or three times, until sufficient experience has been gained to detect any imperfection in a tracing.

9. Suspect the correctness of any tracing which possesses either of the following features, viz.:—*a.* A rounded summit. *b.* The absence of a well marked percussion wave. *c.* Any tendency about the termination of the down strokes to form horizontal lines on a level with the commencement of the upstrokes instead of maintaining a gradual descent. One or all of these characteristics may be present in a perfectly correct tracing, but they are rare, whilst they may be very easily produced by imperfect application.

The papers are best smoked over the flame produced by burning solid camphor, a large quantity of carbon being evolved. After a tracing has been obtained it may be rendered permanent by passing the smoked paper through a varnish made by macerating one ounce of Gum Benzoin in five ounces of rectified spirit with frequent agitations, for two days, and then pouring off the clear liquor from the insoluble constituents of the gum-resin. This varnish possesses the advantage of drying very rapidly.

CASE OF UTERINE INSTRUMENTS.

Set of Uterine Instruments in Case, consisting of Two Silver-plated Specula, with Introductory Plug (Figs. 2, 3, 4), Uterine Curette and Sound (Fig. 1), Porcupine Quill Handle (Fig. 5), on which can be screwed Sponge Holder, Scarifier and Caustic Holder (Figs. 6, 7, 8), and Candle Lamp with Reflector (Fig. 9). This is a very compact set of instruments, being little larger than a Fergusson's Speculum £5 5 0

DR. BANTOCK'S GYNÆCOLOGICAL CASE.

(Fig. 10.)

WE have made for Dr. Granville Bantock a Gynæcological Case, of which an illustration is appended. It consists of a central upright part, 12 inches long, 4 inches wide and 6 inches deep. On one side at the bottom is a long drawer divided into compartments, one running the whole length and three formed by cross partition, the former intended for long instruments and the latter for stem pessaries, sponge tents, sea tangle tents, etc. On the other side, half way up, is a shorter drawer into which is fitted a set of Neugebauer's specula, trocars, etc. On the top, and occupying three parts of the whole length, are fitted a box for vaginal pessaries, and six bottles for preparations, used in Gynæcological practice, the remainder of the space contains a set of Fergusson's specula, and a pewter box for carrying home small specimens. On each side of this central portion is a flap containing a pocket fitted with the various instruments that may be required, such as sound, uterine redressor, tent introducer, aluminium stem for applying fused nitrate of silver, scarifier, forceps, curved scissors, hysterotome, etc. To one of these is attached the curved top of the case; when closed, fitted with a large pocket, capable of containing tapping tube, syringes, &c. The case is conveniently carried by the strap which passes along the top, and is fastened at each end.

DR. AVELING'S TRANSFUSION APPARATUS.

MODE OF OPERATING.

First place the Apparatus in a basin of tepid water, and, while completely under the water, to fill it and ensure its cleanliness, compress the bulb until all the air is expelled.

The patient having been brought to the side of the bed, and the arm bared, a fold of skin over a vein at the bend of the arm should be raised, transfixed and divided. The flattened vein now brought into view, should be seized with a pair of fine forceps, raised while an incision is made in it, and the bevel-pointed silver tube inserted. In taking this tube out of the basin, it should be kept full of water, by placing the tip of the thumb over its larger opening. While the operator is doing this an assistant should prepare the arm of the blood donor, as in ordinary bleeding, making an incision direct into the vein, and passing the round pointed tube into it, with its point towards the fingers. This person should then be brought to the bedside of the patient and seated in a chair. It is better not to secure the tubes in the veins by ligatures. B represents the hand of an assistant holding the efferent tube and the lips of the small wound together, and A shows the afferent tube secured in the same manner. The india-rubber portion of the apparatus, filled with water, and kept so by turning the cock at each end of it, is now fitted into the two tubes. The cocks are then turned straight and the operation commenced by compressing the india-rubber tube on the efferent side D, and squeezing the bulb, C; this forces two drachms of water into the afferent vein. Next shift the hand D to D' and compress the tube on the afferent side, then allow the bulb to expand slowly, when blood will be drawn into it from the efferent vein. By repeating this process any quantity of blood can, at any rate, be transmitted, the amount being measured by counting the number of times the bulb is emptied.

DR. J. BRAXTON HICKS' TRANSFUSION APPARATUS.

It can be employed for pure blood, for defibrinated blood, and more especially for blood to which Salines are to be added to prevent Coagula.

The Glass Bottle is to hold Phosphate of Soda. The Thermometer to give the temperature of the solution. The Gravimeter to take its specific gravity. The Scalpel will open the veins of both giver and receiver. The Syringe should be warmed before filled. The mode of employing the instrument is as follows :—

Take Crystals of Phosphate Soda (for instance), wash them in clean water, then make a solution of them in hot water at blood heat (98 Fahr^t.), of the Sp. Gr. of the blood, namely 100·50. Make about 4 oz. of this solution. The arm of the blood-giver is then to be tied ready for opening the vein, next the vein of the patient is to be opened and one of the tubes inserted, the vein of the blood-giver is then to be opened and the blood received into a warm clean vessel, into which about $\frac{1}{2}$ oz. of the solution has been placed ; during the blood-flow the mixture should be gently mixed by a silver spoon, piece of wood, etc., whereby coagulation is prevented ; remove the Piston from the Syringe, turn the tap, pour in the mixture to the full, if sufficient ; then Piston is to be replaced. It will displace some of the mixture, which permit ; now turn the tap, press a few drops of the mixture into the end of the vein tube, so as to fill it and thus displace the air, then fit the Syringe into the tube and gently inject ; should intermittent pulse, or dyspnoea arise, then wait, and resume as soon as these symptoms pass off.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

DIEULAFOY'S ASPIRATEUR.

THIS is the simplest form of Aspirateur. *Directions for Use.*—To form a vacuum place the handle of the tap between the two tubes and in a direct line with the piston; then draw the piston up, and fix it in position by giving it a half-turn to the right. The tubes connecting the needle and the weighted end can be alternately opened by turning the handle of the tap opposite each when required.

Price of the above Aspirateur in case, £3 3s.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

POTAIN'S ASPIRATEUR.

THIS is a very convenient form of aspirateur, its chief advantage being that it can easily be attached to any ordinary bottle by means of the india-rubber stopper. *A* represents the canula; *B*, the screw mount to attach to mount *A*; *C*, a mount which is plugged in mount *B* for the purpose of guiding the trocar *D*. The trocar has a ring turned in it near the point, in order to show when partially withdrawn when it is necessary to turn the tap off to exclude air on removal of the trocar.

Directions for Use.—Turn off the tap nearest the tube connecting the trocar; exhaust the air in the bottle by means of the pump (about ten to fifteen strokes will suffice), then turn the tap nearest the pump off, and place the trocar *in situ*. Remove the trocar, taking care to turn off the tap when the turned ring is seen outside the canula, to prevent air getting in the cyst. The tap between the bottle and the trocar should then be turned on, and the fluid will immediately flow in the bottle.

Price of the above Instrument:—

Nickel-plated, in case	£3	3	0
A cheaper form is also supplied at	1	10	0

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

COUDEREAU'S ASPIRATEUR.

THIS instrument is a modification of Dieulafoy's Aspirateur, from which it differs in having a revolving disc at the lower end, in place of the two way tap on the original instrument.

Directions for Use.—To form a vacuum draw the piston rod up to the top of the glass barrel, and fix it by giving it a half turn to the right; it will, by this action, cause the slot on the piston rod to fix itself on the corresponding screw at the top of the aspirateur. In the revolving plate a slot is cut in which a pin travels; by means of this pin it can be seen when the tubes connected with the aspirateur are open. For example, when the pin is opposite the tube to which the needle is attached, it is open; when it is between the tubes a vacuum can be caused, as the tubes are then both closed; and if it is opposite the weighted tube, the exhausted fluid can be expelled into a receiver for waste.

This apparatus can also be used to inject a cyst after exhaustion.

Price of the above Aspirateur, in case, £3 15s.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

RASMUSSEN'S ASPIRATEUR.

WITH BAYONET-JOINTED TROCARS.

THIS aspirateur can be exhausted by twenty strokes of the pump, and a vacuum maintained by giving a few occasional strokes as the fluid appears to pass slowly.

The Bayonet-jointed Trocars (which were first introduced by us in this country) have the advantage of allowing the trocar point to be withdrawn in the canula which, by this means, presents a guarded end; corresponding holes in the inner tube are brought opposite those in the outer tube, when the trocar is drawn into the bayonet catch.

Price of the above Aspirateur, in case, £4 10s.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

THE PORTABLE BOTTLE ASPIRATOR.

Directions for Use.—Attach the elastic tube with intermediate glass tube to the small branch of the stopcock on the top of the bottle; to this tube the needles are fixed. Insert the elastic tube with intermediate stopcock into the lower part of the bottle; this tube serves to empty the bottle: and lastly, attach the tube for the air-pump to the large branch of the upper stopcock, and the apparatus is ready for use. The lower stopcock being turned off, and the upper stopcock turned on (towards the needle), the bottle is exhausted by eight to ten strokes of the piston. The needle is then introduced to just beyond the holes at the side, the upper stopcock turned on (towards the pump), and the needle pressed forward. If there is fluid it will immediately be seen to pass the glass tube. When the bottle is full reverse the stopcock, detach the tube of the air-pump and open the lower stopcock, when the fluid passes out of the bottle. When the piston of the air-pump becomes dry, put some oil to the leather to soften it.

Price of the above Instrument, in case, £5 5s.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

DESCRIPTION AND DIRECTIONS

FOR THE USE OF

PROFESSOR LISTER'S STEAM SPRAY APPARATUS,

For producing an Antiseptic Atmosphere.

THE above engraving represents the boiler removed from the lamp in order to show the arrangement for lighting and extinguishing the spirit flame. The dotted lines show the boiler in position when ready for use.

The Boiler is made of solid brass, to which the various parts

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

are brased in the fire, this renders it most durable, and most suitable for hospital use. It is provided with a screw stopper **F**, safety valve **G**, stop-cock for steam tube **H**, and the spray tube, which can be elevated or lowered so as to disperse the spray either upwards or downwards.

To Charge the Boiler. Remove the screw stopper **F**, and fill it with clean hot water, allowing for each hour's use about 12 ozs. Replace the stopper.

The Spirit Lamp. Remove the stopper **C**, and nearly fill the lamp with methylated spirit, and replace the stopper. Light the small wick **D**, open the snuffers **EE**, when the small flame lights the circular wick, the flame of which heats the central tube, and converts the spirit into vapour, which escapes from several small holes near the top of the tube, where it must be lighted. When the apparatus is not in use, cap **B** is placed over the central tube and the small wick to prevent evaporation of the spirit. After the lamp is lit and the boiler charged with water, place the latter on the lamp; a small tongue on the lower part of the boiler resting in a socket on the lamp behind the bottle, and another is secured by the clip **A** at the opposite side under the handle of the boiler.

Advantage of the Snuffers of the Lamp. When an operation is finished, the snuffers are closed and thereby the central light is extinguished, the small wick alone remaining alight. After this the stop-cock of the steam tube should be closed. The central wick can be instantly lighted by opening the snuffers, when in a few minutes sufficient steam pressure is produced to commence another operation.

SPECIAL INSTRUCTIONS.

To produce a perfect spray it is necessary that every part of the apparatus should be in good working order. There are three cotton wicks in the lamp ; a small one in the movable tube, one outside and one inside the central tube ; the two latter must be of equal length. Care must be taken to adjust the central wick around the tube, it must project evenly and but very little, in order to give but a small flame around the central tube, because if the flame is too large the clamps cannot extinguish it.

The three wicks have to be frequently changed, as the methylated spirit clogs them when they have been used a few times, and they lose their absorbing power. It is also advisable to place a piece of sound sponge in the small glass bulb at the end of the suction tube, in order to prevent minute particles of dust entering and obstructing the fine holes of the spray tube. It may also be necessary to pass a fine silver wire through the hole of the steam pipe in order to clear it. The stop-cock of the steam tube should also be occasionally seen to ; it can be taken out, thoroughly cleansed and greased.

BATTERIES.**STÖHRER'S SMALLEST AND VERY PORTABLE
INDUCTION APPARATUS,***With one Closed Cell.***Price £3 18s.**

The Battery, a section of which is figured above, consists of a vulcanite case, in which is a carbon cylinder, reaching from the bottom to the top. The top or lid screws off. When the top with india-rubber cover is screwed on, it presses the carbon on a platinized conducting wire, which passes through the bottom of the apparatus. The conducting wire ends as a projection screw, which establishes the connection at the bottom of the apparatus. The vulcanite case has an enlargement at the top, which leaves a free space between the carbon and outside of the case, which is filled with powdered carbon for the reception of concentrated solution of chromic acid.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

SMALLEST INDUCTION APPARATUS,
With Two Closed Cells.

Price £5 5s.

This Apparatus contains two batteries of the same construction as described in Apparatus on page 238.

When both zinc pieces are placed in the slits and connected with the movable arms, the strongest action is produced. If only one element is to act, slide the connecting arm of the other element on the split connecting wire, which is placed for this purpose at the posterior side of the case. In all other respects the elements are treated the same as described in the preceding pages.

The hammer of the interrupter carries a screw with platinum point, which is pressed by a brass spring against a springy piece of metal covered with platin. The latter is supported at the front part by a regulating screw, by which the distance of the hammer from the electro-magnet can be regulated. Respecting the play of the interrupter, the necessary care required for regulating the minute distance between the hammer and the electro-magnet, the same rules must be observed as explained before. When the platin of the screw in the hammer has worn, it can be made good by screwing the screw a little forward; if the platinized contact place of the piece behind the hammer has worn, it can be shifted and a new contact place is thus obtained.

If the supporting screw of the piece of metal behind the hammer is screwed so far back as to set it free, it takes part in the vibrations (is yielding), which causes a very soft and regular play of the hammer, the little shocks of which are hardly felt.

The two brass screw heads in front of the Apparatus serve for the reception of the two conducting cords. By turning the movable arm to the letter S, the secondary current is directed to them; if towards the letter P, the primary current. The secondary current is regulated by shifting the graduated wooden stem, the primary current by the metal stem.

DR. E. STÖHRER'S INDUCTION APPARATUS.

*The One-celled Portable Induction Apparatus.*

Price £4 10s.

The Single-Celled Induction Battery consists of two parts. In the left-hand compartment is a pair of carbon and zinc, without any porous cell. In the middle is a carbon-cylinder filled with sand, and closed with a glass stopper; the sand is moistened with a little chromic acid (from 10 to 12 drops lasts for two or three months). If the battery be used every day continuously, the chromic acid must be renewed as often as the diluted sulphuric acid.

The zinc surrounds the carbon-cylinder, and is prevented from touching it by glass insulators. The zinc and the carbon are connected by copper wires, screwed into brass clamps, with the induction coil, which occupies the other half of the box. The copper plate, which by the help of a screw is kept in direct contact with the carbon, must be kept bright and clean. The glass vessel contains diluted sulphuric acid, 1 part to 6; it slides vertically up or down, and can be fixed in any position. By this arrangement the acid can be put as much or as little in contact with the battery as may be required; in the lowest position of the glass, the battery no longer acts at all. As, in the latter case, the acid only fills the lower third of the glass, the apparatus can be carried about without danger of spilling it.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

The Double-Celled Portable Induction Apparatus.

Price £6 10s.

The battery of this apparatus consists of two pairs of the same construction as in Apparatus on page 240. With the assistance of the two long brass connectors (which will be found in the box at the side of the apparatus) the two pairs can be made into one of double surface, by connecting carbon with carbon, and zinc with zinc.

To bring both elements into action, connect, with short brass connectors, the carbon of the one with the zinc of the other element. If it is desired to use one only, one pair can be left out by inserting only one of the long connecting brasses.

These connecting brasses are to be inserted under the small screw-heads, which are in those larger screw-heads which hold the copper wires of the zincs and carbons. The latter must, however, be previously tightly screwed down before any of the connecting brasses are inserted.

The course of the current will be understood if we remember that the first carbon and the last zinc are permanently connected.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

STÖHRER'S CONSTANT CURRENT BATTERIES.

(PLATES OF ZINC AND CARBON.)

*The Drawing represents a Portable Battery of 20 elements, zinc and carbon.***Price £8 8s.**

DESCRIPTION.—These comparatively small and light Instruments are intended for use in visiting practice, and can be easily carried by hand or in the carriage.

The pairs are zinc and carbon plates, 12 centimetres in height, and of a proportionate width ; these are suspended on a connector, which is let into a wooden bar, to which the elements are suspended. On this wooden carrier there slides a traveller, which contains, on its under side, the metals for making the current, and, on the upper side, the commutator, for changing its direction. By pushing the traveller to the right the number of cells yielding the current is increased without any interruption of the stream.

The vessels for the acid are vulcanite cells, which can be lifted up or down, so as to throw the battery into or out of action. It is not easy to spill the acid, as the cells are only half filled ; but should the accident occur, we must pull out a little vulcanite stopper at the left side of the battery, and slowly tilt the instrument, so as to allow the acid to run out.

The conductors and electrodes are kept in a small box in the hollow lid of the instrument. Carbon points are usually employed, but, if preferred, sponge-electrodes, in large handles, can be supplied.

These batteries are made with 20 cells, and larger ones with 30 cells. Price, £11 11s.

BATTERY FOR HOSPITAL USE.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

STÖHRER'S COMBINED APPARATUS,
INDUCTION AND CONSTANT CURRENT COMBINED.

The above Engraving represents a battery of 20 pairs, of the same size as the Portable Battery described on page 242, and an induction apparatus, with one cell, as described on page 140.

Price £12 12s.

The cells are made of vulcanite. They are raised by the two handles, one of which projects at each side of the case, and are kept at the raised position by giving the handles a half turn when raised to the highest point.

The carbon and zinc plates are screwed in pairs on brass hangers, which are suspended in the slits of the wooden bar or element carrier, the zinc plate hanging in one cell, and the carbon plate in the cell next to it.

A wooden slide or traveller, with two brass springs underneath it, connects two elements opposite each other. So many elements are brought into action as are denoted by the figure on the element carrier, over which the slide must be placed so that the figure is exactly under its centre.

The battery is open at the right side, the first two plates on the left side are connected by wires with the commutator.

Charging the battery must be done with the cells raised. Put in each cell a pinch of sulphate of mercury, and fill each cell with

diluted sulphuric acid (one part acid to 8-10 parts of water) to within an inch from the top.

Or the following solution may be used instead :—Prepare a solution of zinc in spirits of salts, dilute this solution with double the quantity of water, and filter it ; add a little sulphuric acid, so much until the fluid becomes clear. This chlorzinc solution acts a little weaker, but is, however, very constant, and perfectly free from smell.

The zinc plates must be kept well amalgamated with either of the two solutions.

The Induction Apparatus is of the same construction as the One-Celled Apparatus described on page 140, with a separate cylindrical element. The hole in the carbon is filled with sand, on which is poured from 8 to 10 drops of concentrated solution of chromic acid. The glass cylinder is filled one-third with diluted sulphuric acid (one part acid to 6 to 8 parts water), so that when in the lowest position the carbon and zinc cylinder do not touch the fluid.

The two insulated conducting cords are fixed in the two clamp screws, right and left of the commutator. When the small brass handle of the cylinder of the commutator is placed upright, the current is interrupted ; when the handle is turned towards the front, the left side is the positive pole (carbon). When the handle is turned towards the inductor, the right side is the positive pole.

The connection of one of the three currents is *only then established* with the commutator, when the brass pin (which is found at the right side of the commutator) is placed in one of the three holes, marked K, P, S :—K, constant current ; P, primary induction ; S, secondary induction current.

The primary current is regulated by drawing up the graduated metal stem by the small brass handle ; the secondary current by drawing up the graduated wooden stem by the black wooden handle.

As by means of the arrangements for regulating the strength of the three different currents, they can be made to produce almost the same physiological action ; the method of making connection of any current with the commutator by inserting the brass pin, offers to facilitate the application, in rapid succession, of any desired current in any direction without having to move or change the position of the conductors, which, as is well known, produces in many cases good results.

Larger batteries are made in the same form as described above, containing a two-celled induction apparatus, with a thirty-celled constant current battery. *Price, £17 17s.*

BATTERY FOR GALVANIC CAUTERY.

It consists of four Bunsen's cells (carbon and zinc). To charge the battery unscrew the screws which hold the copper connections, and bend these connections back over the edge of the case to be enabled to take out the cells. Take out the porous cells with the carbons in them, and fill them with pure nitric acid to within one inch of the top, then replace them in the vulcanite cells between the two zinc plates. Fill the vulcanite cells with diluted sulphuric acid : viz., one part of acid to eight or ten parts of water (by means of a funnel) level with the nitric acid in the porous cells. Care must be taken not to mix the two fluids. Replace the copper connections—commence at the left side—connect the first wire on left side of the case with the first pair of zinc plates ; the second wire with the carbon plate in first cell ; the next wire with zinc plates of next cell, and so on until the fifth wire is connected with the carbon of the fourth cell. The battery is then ready for use, and the lid may be closed. Insert the conducting wires in the two brass heads in front of the case, and attach to them the cautery instrument intended to be used, as shown in the engraving.

The four brass studs in front of the case are the terminals of the elements. If the lever is placed on the stud at the left side, one cell is brought into action ; if on the stud at the right side, the four cells act on the instrument. This must be specially noticed, as instruments with fine platinum wire require only the power of one cell, and would be destroyed by too great a heat if two or more cells were brought to act upon it. After use, the cells should be emptied at once, to avoid useless destruction of the elements. This is done in the same manner as in charging. The connections are unscrewed and turned back, the porous cells are taken out, and the nitric acid poured back into one of the bottles supplied with the battery. The sulphuric acid may be thrown away, as the acid for a fresh charge is inexpensive. The same acids may, however, be used several times, and only sufficient fresh acid added to replace what has been used up.

The carbon plates should be placed in clean water for a few hours, and not be replaced in the cells until they have been thoroughly dried in the air. The zinc plates need only be rinsed in water and dried.

Each cautery instrument is provided with a contact breaker, which consists of a slide on the handle of the instrument. The current is not closed before the instrument is to be used. A trial, however, should be previously made to ascertain if the necessary elements are connected to produce a red heat.

„ 4. Large „ „	1	10	0

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

Fig. 1.—Galvanic Ecraseur. Fig. 2.—Side view. Price, £4 4s.

The instrument consists of four separate and separable parts :—

a, The handle ; *b*, a screw on which travels a clamp (*h*) ; *c*, canulæ through which the wire passes ; *d*, platinum wire loop ; *e*, ivory “interrupter” to connect or break the galvanic current by slight pressure of the thumb ; *f*, sockets into which the canulæ can be fixed by screws ; *g*, receptacle for connecting wires from battery ; on the long screw (*b*) rides the clamp (*h*), between the jaws of which the ends of the platinum wires can be fixed by a screw.

MIDDELDORPF'S BATTERY FOR GALVANIC CAUTERY.

MODIFIED BY JOSEF LEITER.

The battery consists of four Bunsen's elements. Each element consists of two zinc and one carbon plate, 23 cent^e. high and 15 cent^e. wide. The elements are suspended on an insulated metallic rod, which terminates at each end in a vulcanite handle, by which they can be lifted in and out

8, *DUKE STREET, MANCHESTER SQUARE, W.,*
and 241, *WHITECHAPEL ROAD, E., LONDON.*

of the vulcanite trough. The trough is divided into four compartments, in each of which is placed a porous cell. The zinc and carbon plates are mounted on solid brass collars which slide on the rod (element carrier) and are kept from contact by vulcanite rings. They are screwed together by the vulcanite handles at each side of the rod. At the sides of the trough are metallic supports for the element carrier. The bolt is fastened by passing it through and giving it a half turn. The whole apparatus can then be carried safely by the two handles. Connections of the elements are made with brass connectors, which are fixed by means of screws to the brass collars. Connectors and collars are marked with corresponding numbers, so that no mistake can be made when connecting the elements. The battery put together as above described is ready to be charged. Fill the porous cells with about 15 ozs. of nitric acid, and each vulcanite cell with 20 ozs. diluted sulphuric acid, one part acid to eight parts of water. The action of the battery commences at once. The conducting cords are fastened with screws to the collars of the plates, numbered respectively 1, 2, 5, 8, and 11; if the cords are connected with collars 1 and 2, only one element is brought into action, if with 2 and 5 two elements, 2 and 8 three elements, 2 and 11 four elements. The cautory instruments are attached to the cord by two mounts with square holes and fixed to them by screws.

Price of Battery, with Conducting Cord, £14.

- „ 4. Sayre's Tripod, showing patient in the act of Suspension.
- „ 5. Application of Jury Mast (side view).

(Extracted from the transactions of the American Medical Association.)

In a discourse, on the above subject, before the American Medical Association, Dr. Alfred C. Post, of New York, says :

“I consider that this principle, introduced by Dr. Sayre, constitutes an epoch in the treatment of this very distressing form of disease.”

After seconding the motion, to refer Dr. Sayre's paper to the committee of publication, Dr. Lee, of Philadelphia, says :

“The idea which underlies this mode of treatment is undoubtedly the true principle for the treatment of Pott's disease. We have done wrong in considering it a purely constitutional affection. We must look upon it as a surgical disease, and treat such cases much as we treat a fractured limb. It is this that Dr. Sayre has done in applying his plaster bandage. He has treated a carious spine as any one of you would treat a broken leg, and

in doing so has achieved the results which he has shown you, which we must all admit to be wonderfully successful. I have not yet myself put this plan in practice. I have been so long making use of other appliances having the same end in view, have become so accustomed to them, and so well satisfied with them, that I have hesitated to make a new experiment; but after hearing the demonstration of to-day, I feel that I shall be wanting in justice to my patients if I do not at least make the effort to use it."

PRICES OF DR. L. A. SAYRE'S APPLIANCES FOR
TREATING SPINAL DISEASES BY SUSPENSION.

	£	s.	d.
Tripod in Japanned iron bayonet-jointed, with pulleys, cross-bar, two chin bands, and one pair of arm bands, as Figs. 1 and 4	5	10	0
Tripod in Bamboo, jointed with sliding brass caps to fix the joints, two chin bands, one pair of arm bands	6	10	0

TRUSSES

By which ruptures, to which man is liable, are restrained from lapsing. As frequently much difficulty has been experienced to restrain a rupture, many ingenious contrivances have been, from time to time, invented with the view of overcoming these difficulties. But experience has proved that, in many cases where the most complicated and ingenious mechanism had failed to restrain a rupture, a well-adjusted covered steel spring, with suitable pad or pads, answered best the purpose. We therefore name those only which are suitable for most cases.

Fig. 7.

Dr. HENRY DICK'S TRUSS.—This Truss has been specially made upon the principle, that it is necessary to have two springs for each truss—i.e., one spring representing the elasticity of the body, the other acting on the oblique surface, where a steady pressure is wanted to keep the hernia up. Dr. Dick has observed, that trusses made with one spring have the disadvantage of being easily displaced when the patient assumes either the sitting or stooping positions, which disadvantage is entirely obviated by his own truss. There is also an improvement in the pad, the pressure upon which is not directed upon the centre, but between the centre and the lower edge. The spring upon the pad is specially shaped to prevent displacement, and at the same time keep a steady and even pressure upon the hernial opening in any position.

We can with confidence recommend this Truss, it having been successfully applied in the most severe cases for the last fifteen years, and in scrotal hernia, where other trusses have utterly failed to afford relief, has been used with the most satisfactory results, thus proving it to be the most efficient Truss yet invented.

LESLIE'S PLIABLE PLAISTER.

A novel kind of Adhesive Plaister, which will be found superior to those in ordinary use. Its recommendations are as follows:—It is readily applied and adheres firmly. Being limp it can be accurately adapted. It is strong in texture, made of superior fabric, does not irritate, and is not injured by keeping. It is useful in any climate.

It is used and approved by the Medical Profession, and is employed in several London Hospitals.

Sold in Tins at 9d., 3s. and 5s. 6d. each.

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

ON

ANTISEPTIC SURGERY.

BY JOHN BISHOP, M.D. EDIN.,

MASTER IN SURGERY ; FELLOW OF THE ROYAL COLLEGE OF SURGEONS,
EDINBURGH ; MEMBER OF THE ROYAL COLLEGE OF SURGEONS,
ENGLAND ; LICENTIATE OF THE ROYAL COLLEGE OF
PHYSICIANS, EDINBURGH ; ASSISTANT SURGEON
TO THE ROYAL INFIRMARY, EDINBURGH ;
ETC.

Reprinted (with additions) from "Swain's Surgical Emergencies" (2nd Edition, 1876), published by Messrs. J. & A. Churchill, London, by Messrs. KROHNE & SESEMANN, 8, Duke Street, Manchester Square, W.

General Remarks—Carbolic Acid—Antiseptic Gauze—Gauze Bandage—Antiseptic Atmosphere—Steam Spray Apparatus—Boric Acid—Salicylic Acid—Chloride of Zinc—Iodoform—Oil-Silk Protective—Drainage Tube—Catgut Ligatures—Carbolized Silk Sutures—Abscesses—Precautions before and during an Operation—Dressing after Operation—Compound Fractures—Dressing in Compound Fractures—Operation on Parts affected with Sinuses—Abscess by the Side of Rectum.

THE mere use of antiseptic dressings will not of itself yield successful results to the surgeon. He must give unremitting attention to all the minutiae of application which have been deduced from the germ-theory of putrefaction, upon which the treatment is based. The results of true antiseptic management will be found to be such as would repay the expenditure of far more effort than will have been required for their attainment ; to say nothing as to the average saving of time, and the relief derived from diminished anxiety.

The following is a short account of the antiseptic treatment employed by Professor Lister, of London, in 1879 :—

8, DUKE STREET, MANCHESTER SQUARE, W.,
and 241, WHITECHAPEL ROAD, E., LONDON.

The five antiseptics which have been found most useful are—Carbolic Acid, Boric Acid, Salicylic Acid, Chloride of Zinc, and Iodoform.

Pure carbolic acid—remarkable for its power of destroying low forms of life—is, on the whole, the most efficient antiseptic for general purposes. Its energetic action on the epidermis makes it the best agent for cleansing purposes. In the form of one to twenty watery solution, it is used for purifying the integument of the part to be operated upon, and the sponges, instruments, etc. As a one to forty solution, it is used for washing sponges during an operation, for the hands of the operator and assistants, and for the changing of dressings.

The volatility of carbolic acid renders it invaluable for dressing hollow wounds and abscesses. It is the active constituent of the ordinary dressing—antiseptic gauze—which is applied, in eight layers, of size proportioned to the expected amount of discharge. A piece of thin mackintosh cloth (technically called hat-lining) is interposed beneath the outer (eighth) layer of gauze, to prevent the discharge from soaking directly through the centre of the dressing, washing out the portion of acid there stored up, and thus giving putrefactive organisms direct access to the cavity. Further, as carbolic acid is given off very slowly by the gauze at the ordinary temperature of the air, it is quite possible that septic organisms, accidentally adherent, might be conveyed to the wound by the surface of the dressing itself. To guard against this mishap, that portion of the inner layer of gauze which will lie opposite to the wound is damped with the promptly acting one to forty solution, or else a small piece of gauze wrung out of the same solution is applied before the ordinary eight-fold dressing.

The antiseptic gauze is convenient in the form of bandage, which not only applies itself, and retains its position better than a calico bandage, but is often a valuable addition to the antiseptic quality of the dressing. In the case of stumps, in which there is a tendency to retraction of the soft parts, the antiseptic bandage enables the surgeon to overcome what would otherwise be a considerable difficulty in the treatment of the case.

It is not sufficient to have a reliable dressing, and to be able to purify the skin and the instruments. There must also be an anti-

septic state of the atmosphere, which cannot fail to gain access to the wound or abscess during the operation, or the changing of dressings. This is provided in the form of a spray of one to forty carbolic acid solution, for which a steam spray apparatus is the most easily managed and efficient instrument at present available.

When the spray is suspended during an operation, or the changing of a dressing, the wound should be covered with a piece of sound calico moistened with one to forty carbolic acid solution, which, for convenience, is termed the guard. Of course, neither spray nor guard is required for superficial sores.

Boric acid is a valuable antiseptic, but its non-volatility prevents its being used for the dressing of hollow wounds, and for the spray. It is bland and unirritating as compared with carbolic acid, and is therefore particularly useful as a dressing for superficial wounds and sores. It is employed in the form of a saturated watery solution; as boric lint, which contains about half its weight of the crystals of boric acid; and as an ointment which may be prepared by mixing one part of powdered boric acid with five or ten parts of unguentum petrolei, according to the strength desired.

Salicylic acid, which was introduced into surgical practice by Professor Thiersch, of Leipzig, at the suggestion of Professor Kolbe, has not been adopted by Mr. Lister as an ordinary dressing, having been proved by him to be inferior to carbolic acid in its power of destroying bacteria, though very efficient in preventing chemical fermentations. He has, however, found salicylic acid to be of great use in certain exceptional cases, where irritation of the skin occurs after a gauze dressing has been left on for several days. The form of eczema thus arising was formerly attributed by Mr. Lister to the irritating effect of carbolic acid on sensitive skins, but the invariable disappearance of the affection after one or at most a few applications to the inner layer of the gauze dressing of a small quantity of salicylic acid, suspended in one to forty carbolic acid solution, has shown the irritation to be due to an alteration in the effused serum, brought about by some other agency.

Chloride of zinc has the remarkable peculiarity among anti-

septics of producing such an effect upon the tissues of a recent wound, when applied in a watery solution of about forty grains to the ounce, that, as the result of a single application, the cut surface, inough not presenting any visible slough, is rendered incapable of putrefaction for two or three days, notwithstanding its exposure to the influence of septic material. The patient is thus tided over the dangerous period preceding granulation, during which the divided tissues are most prone to inflammation and the absorption of septic products. Hence this salt, though very irritating and non-volatile, and therefore not adapted for general use, is of the highest value in circumstances which render it impossible to exclude septic organisms in the after-treatment; as, for example, after the removal of tumours of the jaws, or operations about the anus, and after amputations or excisions in parts affected with putrid sinuses. The solution is freely applied to all textures, including bones, by means of a piece of lint held in dressing forceps. Sinuses are injected at the conclusion of the operation by means of an ordinary brass syringe.

Iodoform, which has the advantage over chloride of zinc of being painless, has lately been sprinkled over the surface of putrid ulcers, in order to purify them prior to the application of the antiseptic dressing.

In order to obtain the best results from the antiseptic treatment, it is desirable to protect the healing parts from the irritating influence of the antiseptic itself, which, in the case of carbolic acid, would often prevent cicatrisation altogether, and which, even with the much blander boric acid, is better avoided. This protective is effected by interposing a layer, consisting of some material unirritating in itself, and as far as possible impervious to the antiseptic agent.

The protective commonly used is composed of thin oil-silk, varnished with copal, and then coated with a layer of dextrine. The dextrine allows the oil-silk to become uniformly wetted by the antiseptic solution, into which it is dipped at the moment of application. It is obvious that the antiseptic dressing proper must extend a considerable distance beyond the protective, or putrefaction may spread under the latter, in spite of the dressing which is above it.

The application of antiseptics to the raw surfaces of a wound causes a certain amount of irritation, and leads to an unusually abundant discharge of serum ; so, in order that this may not be pent up, and occasion inflammation from tension, a very free outlet must be provided. This is effected by means of Chassaignac's drainage tubing, of which the red is preferable to the black variety. Four sizes are used, having an external diameter of $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, and $\frac{1}{32}$ inch respectively. Large holes are cut in the walls, so as to allow the discharge to reach the interior of the tube ; and two loops of silk thread, knotted at the ends, are attached to opposite sides of the margin of the outer extremity of the tube to prevent its displacement. The outer end is cut either transversely or obliquely, according to the direction of the cavity, so that the orifice of the tube may be flush with the integument.

When abscesses are opened, a drainage tube should be used, of a length equal to the depth of the cavity, and of a calibre proportioned to the quantity and thickness of the pus discharged. The tube should be shortened from time to time as the cavity becomes smaller.

Horsehair, which has been soaked for a few minutes in one to twenty carbolic acid solution, constitutes an efficient drain for operation wounds, etc. As the discharge of serum diminishes, the drain may be lessened by removing a few hairs at each dressing. The drain may be partially drawn out of the wound and shortened when expedient. In large operation wounds, it is often desirable to use both drainage tubes and drains of horsehair. In these circumstances, the tubes are discontinued before the horsehair drains.

For arresting arterial hæmorrhage, the prepared catgut used antiseptically combines the security and universal applicability of the ligature with the virtual absence of any foreign body from the wound. The vessel is tied in the usual way, but the ends of the catgut are cut off near the knot.

The catgut may be conveniently carried in the pocket-case in one of Mr. Lister's catgut-holders. As the right preparation of the catgut is a matter of very great importance, it is best to obtain it ready prepared, along with the other antiseptic materials.

As metallic sutures are liable to catch in the dressings, car-

bolized silk sutures are used with advantage. They are prepared by passing ordinary ligature silk through melted bees'-wax, containing ten per cent. of carbolic acid. The superfluous wax is wiped off from the warm thread as it is drawn out from the mixture. The antiseptic property of the silk is conveniently retained by keeping it in a stoppered bottle or wrapped in antiseptic gauze.

Metallic sutures are used with the lead buttons to constitute "stitches of relaxation" when the ordinary sutures are subjected to much tension. Horsehair is very useful as an intermediary suture when accuracy of apposition of the edges of a wound is desired. Horsehair sutures are serviceable for stitching the mucous membrane to the skin in plastic operations on the lips, etc. Long hairs from the tail of a stallion are the best for surgical work. The prepared catgut may be used for sutures or drains in cases where its rapid absorption is not likely to be disadvantageous.

DIRECTIONS FOR SPECIAL CASES.

I. *Abscess.*

This is the simplest case for antiseptic treatment, the antiseptic not being applied at all to the affected tissues, but being used merely to prevent the access of septic mischief from without.

Carefully select the spot for incision with special attention to its distance from a source of putrefaction,* so that the dressing may extend freely beyond the incision in every direction. The skin, the knife, and the operator's fingers having been cleansed with one to twenty carbolic acid solution, after shaving off hairs from the integument, if necessary; let the spray play effectively on the part, then make an incision in the selected position, and of such a size as will easily admit the drainage tube; press out the pus;† insert the drainage tube, and extend the loops of silk in opposite directions; apply over the incision a small bit of gauze wetted with carbolic acid solution; cover this with a large dressing consisting of eight folds of gauze and the enclosed piece

* So important is this that it might lead to the refusal to operate—*e.g.*, in a case of spinal abscess pointing near the anus.

† In strumous abscesses it is often advisable to apply a sharp spoon to the walls of the cavity.

of mackintosh, as above described ; and lastly, secure this with a well adjusted gauze bandage and with safety-pins, which must not penetrate the centre of the mackintosh, or its efficiency will be destroyed. When the abscess is situated in a part where the dressing is particularly liable to disturbance from the movements of the patient (as at the groin, in case of psoas abscess), great additional security is afforded by the employment of a turn or two of elastic webbing applied so as not to occasion uneasiness or œdema of the limb. This elastic bandage follows the movements of the patient, and insures the constant application of the dressing to the skin. If it is desirable to explore the abscess cavity with the finger, special care must be taken that the latter be well cleansed about the nail and elsewhere with the carbolic acid solution, immediately before introduction.

Next day let a hand be placed so as to keep the dressing in position whilst the pins are being removed and the bandage is being cut. Direct the spray towards one side of the dressing, which must then be cautiously raised, so that the spray may pass into the angle between the dressing and the skin. Remove the drainage tube under the spray ; cover the incision with a guard wash the drainage tube and the skin with one to forty carbolic acid solution : again direct the spray to the incision, remove the guard, insert the tube, and dress as above described.

As the discharge diminishes, dress the case every two, three, four, five, or six days, as required, the general rule being that the dressing is changed, if discharge is found to have made its appearance beyond it at the usual time of the surgeon's visit. Give the same amount of care to every dressing until cicatrization is complete ; this being the only trustworthy evidence that the sinus is closed. In cases of chronic abscess, due to caries of vertebræ, or to morbus coxæ, keep the patient in bed six weeks after the abscess is closed. In the latter cases, keep on the long splint during the whole period.

II. *Operations on parts where the skin is unbroken.*

These cases come next in the order of simplicity of treatment, the essential object being, as in abscesses, to prevent the

introduction of septic organisms during the operation ; although the divided tissues are necessarily more or less exposed to the influence of the antiseptic in the spray and the sponges, etc.

Prepare the skin, the hands of the operator, and the instruments as above ; conduct the operation as usual, but keep the spray at work until the dressing has been applied—of course, using the guard if the spray be suspended.

When an instrument has been laid aside during the performance of an operation, it is an essential point, very apt to be overlooked, that before being reintroduced into the wound the instrument should be again thoroughly cleansed with the carbolic acid solution.

After securing the vessels, adjust a drain, and stitch up the wound ; then dip into the solution a piece of protective, large enough just to cover the incision, and lay it upon the wound ; over this apply a piece of gauze wetted with the solution, and the usual well-overlapping dry gauze dressing. Change the dressing next day, and afterwards dress more or less frequently, according to the amount of the discharge.

In amputations apply a gauze dressing large enough to wrap round the limb, and to turn up over the face of the stump, like the wrapping at the end of a parcel.

In primary amputations, and in amputations through limbs above the seat of putrid discharge, cover the contused or putrid parts with a towel wrung out of one to twenty carbolic acid solution, so that the sound parts may not become contaminated during the operation.

III. *Accidental wounds, including compound fractures and dislocations which do not require amputation.**

Here, opportunity having been afforded for the entrance of septic material either in the infliction of the injury or subsequently, before the case is seen by the surgeon, the antiseptic must be applied to all the recesses of the wound, in order to counteract

* Experience will soon teach the surgeon that he may save, under the antiseptic treatment, many cases that would require amputation without it.

the mischief which has so entered. For this purpose a strong antiseptic solution must be used, but while it must be introduced among the blood-clots in the recesses of the wound, it is very undesirable that it should pass unnecessarily into the cellular tissue. In ordinary circumstances the one to twenty carbolic acid solution is employed, but instead of forcing it into the wound generally, by means of a syringe, it is better to apply it to the various irregularities of the injured part by a flexible catheter adapted to the syringe with caoutchouc tubing. When several hours have passed after the infliction of the injury, Mr. Lister has for several years used a still more powerful solution—viz., one part of carbolic acid to five parts of methylated spirit.

These operations are conducted under the spray, after cleansing the skin with the one to twenty carbolic acid solution. If a fragment or an end of a bone is projecting, it is well washed with the same solution and returned, in some cases after sawing off its extremity; but reduction is never effected until the depths of the wound have been injected, and, of course, loose fragments and foreign bodies extracted.

It is difficult to assign the precise limit of time when antiseptic treatment must be regarded as hopeless in such injuries. Success has sometimes been obtained as late as thirty-six hours after the accident.

The introduction of stitches should always be avoided in this class of injuries, whilst in some cases a drainage tube should be inserted; and if the wound is very small, it should be enlarged to prevent tension from the accumulation of serum.

The dressing is then applied, as in the last class of cases, the folded gauze being made to envelop the limb for a considerable extent above and below the injured part, in accordance with the large amount of bloody and serous discharge to be anticipated. A gauze padding for the splints in the vicinity of the injury is also often valuable as an additional precaution.

The dressing should always be changed on the following day; but afterwards, if all proceeds satisfactorily, the intervals between the dressings are to be increased as the discharge diminishes. It must, however, be borne in mind, that from the very nature of

these cases—as some organisms in the recesses of the wound may occasionally elude the action of the antiseptic—success cannot be reckoned on with the same certainty as in the two former classes.

IV. *Operations through parts affected with putrid sinuses.*

These cases present the greatest degree of complexity in the antiseptic treatment. It is hardly to be expected that the putrefaction which exists in the recesses of the sinuses can always be completely eradicated; but in a certain proportion of cases this is effected by the practice recently adopted of scraping away all granulation material from the tracks of the sinuses and elsewhere by means of the sharp spoon, after the example of Professor Volkmann, of Halle, and injecting with the solution of chloride of zinc at the conclusion of the operation.* The chloride of zinc solution is at the same time applied to the cut surfaces, and by this means the patient is saved a great deal of pain and danger, as above alluded to, even should putrefaction ultimately show itself.

The usual external antiseptic dressing is employed in the hope of an aseptic result, while it also protects the atmosphere of a hospital ward from foul emanations in case putrefaction should occur.

In these cases of the recurrence of putrefaction, a dressing of boric lint, or of boric ointment, may often be advantageously substituted for the gauze dressing.

V. *Abscess threatening fistula in ano.*

This particular kind of abscess is of such importance as to deserve special notice here. In consequence of the vicinity of the anus preventing the overlapping of the skin around the wound by the dressing to a sufficient extent to insure absence of putre-

* At one time Mr. Lister recommended the injection of the sinuses before the operation was commenced; but though this is the most effective mode of introducing the solution, it has been abandoned for some time past in consequence of inconveniences having in some cases followed from the solution becoming diffused into the cellular tissue of the part.

faction, the gauze cannot be employed. But the difficulty may be overcome by applying to the anal orifice and surrounding parts a mass of lint soaked with a solution of carbolic acid in ten parts of olive oil, and retained in position by a T-bandage; the patient being directed to draw the pad of lint slightly towards the affected side before defæcation, so that the evacuation may be effected without exposing the wound, and to cleanse the anal outlet with the oily solution before readjusting the pad. The oiled lint is changed about every four hours during the first day; but when the discharge becomes very slight, every twelve hours is sufficiently often. The abscess is opened under the spray as usual, after washing well with the one to twenty watery solution of carbolic acid; and instead of a drainage tube, a bit of lint soaked in the carbolized oil is inserted to prevent primary union. Fætor of the pus on evacuation of the abscess must not discourage the surgeon from continuing the antiseptic measures, for experience has shown that in such circumstances, as well as when the pus is odourless, the usual results of the antiseptic system applied to abscesses may be attained, all further suppuration ceasing, and fistula being averted.

VI. *Superficial Sores.*

If there are sloughs, boric lint moistened with the boric acid solution is often employed, after the manner of the "water dressing." When the sloughs have separated, the granulating surface is dressed with protective and boric lint, or with the boric ointment spread on thin calico. In either case the dressing is to be dipped into the solution before it is applied. In cases of putrid chronic ulcer, the integument is cleansed with the one to twenty carbolic acid solution, iodoform is sprinkled over the surface of the ulcer, to which is then applied a dressing of protective and boric lint. The application of the iodoform may be repeated at the next dressing should it be found that putrefaction has not been eradicated by the first application.
